# Searching for new physics

Many reasons to look for physics Beyond the Standard Model (BSM):

- Higgs mass (hierarchy problem + vacuum stability)
- Dark matter exists
- Baryon asymmetry
- Neutrino masses and mixings

# Searching for new physics

Many reasons to look for physics Beyond the Standard Model (BSM):

- Higgs mass (hierarchy problem + vacuum stability)
- Dark matter exists
- Baryon asymmetry
- Neutrino masses and mixings

So what do we do about it?

- Make new particles at high- $E$  colliders
- Study rare processes at high- $L$  colliders
- Hunt for dark matter
- Look for kooky neutrino physics

# Searching for new physics

# Combining searches I

## Question

How do we know which models are in and which are out?

# Combining searches I

## Question

How do we know which models are in and which are out?

## Answer

Combine the results from different searches

- Simplest method: take different exclusions, overplot them, conclude things are “allowed” or “excluded”
- Simplest BSM example: the scalar singlet model

(Cline, Kainulainen, PS & Weniger, *PRD*, 1306.4710)

## Combining searches II

That's all well and good if there are only 2 parameters and few searches. . .

### Question

What if there are many different **constraints**?

# Combining searches II

That's all well and good if there are only 2 parameters and few searches. . .

## Question

What if there are many different **constraints**?

## Answer

Combine constraints in a statistically valid way  
→ composite likelihood

(Cline, Kainulainen, PS & Weniger, *PRD*, 1306.4710)

## Combining searches III

That's all well and good if there are only 2 parameters and few searches. . .

### Question

What if there are many **parameters**?

## Combining searches III

That's all well and good if there are only 2 parameters and few searches...

### Question

What if there are many **parameters**?

### Answer

Need to

- scan the parameter space (smart numerics)
- interpret the combined results (Bayesian / frequentist)
- project down to parameter planes of interest (marginalise / profile)

→ **global fits**

# Know your (SUSY) scans

## Global fits:

Quantitative?  
per-point: always  
overall: always

Strege et al *JCAP*, 1212.2636

MasterCode, *EPJC*, 1207.7315

## Not global fits:

Quantitative?  
per-point: sometimes  
overall: never

Cahill-Rowley et al, 1307.8444

Silverwood, PS, et al, *JCAP*, 1210.0844

# BSM Model Scanning – Statistics 101

## Goals:

- 1 Given a particular theory, determine which parameter combinations fit all experiments, and how well
- 2 Given multiple theories, determine which fit the data better, and quantify how much better

# BSM Model Scanning – Statistics 101

## Goals:

- 1 Given a particular theory, determine which parameter combinations fit all experiments, and how well  
⇒ parameter estimation
- 2 Given multiple theories, determine which fit the data better, and quantify how much better ⇒ model comparison

# BSM Model Scanning – Statistics 101

## Goals:

- 1 Given a particular theory, determine which parameter combinations fit all experiments, and how well  
 $\Rightarrow$  parameter estimation
- 2 Given multiple theories, determine which fit the data better, and quantify how much better  $\Rightarrow$  model comparison

Why simple IN/OUT analyses are not enough...

- Only partial goodness of fit, no measure of convergence, no idea how to generalise to regions or whole space.
- Frequency/density of models in IN/OUT scans is **not** proportional to probability  $\Rightarrow$  means essentially **nothing**.

# Putting it all together: global fits

## Issue 1: Combining fits to different experiments

Relatively easy – composite likelihood ( $\mathcal{L}_1 \times \mathcal{L}_2 \equiv \chi_1^2 + \chi_2^2$  for simplest  $\mathcal{L}$ )

- dark matter relic density from WMAP
- precision electroweak tests at LEP
- LEP limits on sparticle masses
- $B$ -factory data (rare decays,  $b \rightarrow s\gamma$ )
- muon anomalous magnetic moment
- LHC searches, direct detection (only roughly implemented for now)

# Putting it all together: global fits

**Issue 2:** Including the effects of uncertainties in input data  
Easy – treat them as *nuisance parameters*

**Issue 3:** Finding the points with the best likelihoods  
Tough – MCMCs, nested sampling, genetic algorithms, etc

**Issue 4:** Comparing theories  
Depends – Bayesian model comparison,  $p$  values  
( $TS$  distribution?  $\rightarrow$  coverage???)

# Putting it all together: global fits

**Issue 2:** Including the effects of uncertainties in input data  
Easy – treat them as *nuisance parameters*

**Issue 3:** Finding the points with the best likelihoods

( $TS$  distribution?  $\rightarrow$  coverage???)

# Outline

## 1 The Problem

## 2 Progress

- Gamma-rays
- Neutrinos
- CMB constraints

## 3 Future Challenges

- Respectable LHC likelihoods
- Statistical/numerical issues
- Parameter space  $\rightarrow$  Theory space

# Two different approaches to including astro data in BSM scans

- 1 Just use the published limits on  $\langle\sigma v\rangle$  (or  $\sigma_{\text{SI,SD}}$ )
  - Fast – can cover large parameter spaces
  - Not so accurate – experimental limits are invariably based on theoretical assumptions, e.g.  $b\bar{b}$  spectrum
  - Full likelihood function almost never available
- 2 Use the data points directly in BSM scans
  - Slow – requires full treatment of instrument profile for each point
  - Accurate – can test each point self-consistently
  - Allows marginalisation over theoretical assumptions
  - Allows construction of full multi-dimensional likelihood function

- CMB constraints

## 3 Future Challenges

- Respectable LHC likelihoods
- Statistical/numerical issues
- Parameter space  $\rightarrow$  Theory space

# Gamma-rays

## Gamma-ray annihilation searches in CMSSM global fits:

### Fermi-LAT

Satellite pair conversion telescope

Dwarf galaxy Segue 1

(PS, Conrad et al *JCAP*, 0909.3300)

- Full binned Poissonian likelihood (no  $\chi^2$  approximation)
- Full treatment of PSF *and* energy dispersion (with fast convolution library FLATlib)
- Marginalisation over systematic error on effective area
- Diffuse BG from Fermi-LAT Galprop fits
- Isotropic BG best-fit isotropic power law
- $J$ -factor from Martinez et al (*JCAP*, 0902.4715; best at the time)

# Gamma-rays

## Gamma-ray annihilation searches in CMSSM global fits:

### HESS

Air Čerenkov telescope

Milky Way+Carina+Sculptor+Sag dwarf

(Ripken, Conrad & PS *JCAP*, 1012.3939)

- $\chi^2$ -based analysis using public flux limits
- ‘Milky Way’ = halo just beyond GC (45–150 pc)
- Virtual internal bremsstrahlung from co-annihilation strip models caught at high- $E$  by HESS
- but:  $J$ -factors for Sag dwarf rather uncertain

# Gamma-rays

## Gamma-ray annihilation searches in CMSSM global fits:

### HESS

Air Čerenkov telescope

Milky Way+Carina+Sculptor+Sag dwarf

(Ripken, Conrad & PS *JCAP*, 1012.3939)

- $\chi^2$ -based analysis using public flux limits
- ‘Milky Way’ = halo just beyond GC (45–150 pc)
- Virtual internal bremsstrahlung from co-annihilation strip models caught at high- $E$  by HESS
- but:  $J$ -factors for Sag dwarf rather uncertain

- 1 Halo WIMPs crash into the Sun
- 2 Some lose enough energy in the scatter to be gravitationally bound
- 3 Scatter some more, sink to the core
- 4 Annihilate with each other, producing neutrinos
- 5 Propagate+oscillate their way to the Earth, convert into muons in ice/water

# How to find DM with neutrino telescopes

The short version:

- 1 Halo WIMPs crash into the Sun
- 2 Some lose enough energy in the scatter to be gravitationally bound
- 3 Scatter some more, sink to the core
- 4 Annihilate with each other, producing neutrinos
- 5 Propagate+oscillate their way to the Earth, convert into muons in ice/water
- 6 Look for Čerenkov radiation from the muons in **IceCube**, ANTARES, etc

# Advanced IceCube Likelihood for Model Testing

Simplest way to do anything is to first make it a counting problem. . .

Compare observed number of events  $n$  and predicted number  $\theta$  for each model, taking into account error  $\sigma_\epsilon$  on acceptance:

$$\mathcal{L}_{\text{num}}(n|\theta_{\text{BG}} + \theta_{\text{sig}}) = \frac{1}{\sqrt{2\pi}\sigma_\epsilon} \int_0^\infty \frac{(\theta_{\text{BG}} + \epsilon\theta_{\text{sig}})^n e^{-(\theta_{\text{BG}} + \epsilon\theta_{\text{sig}})}}{n!} \frac{1}{\epsilon} \exp\left[-\frac{1}{2}\left(\frac{\ln \epsilon}{\sigma_\epsilon}\right)^2\right] d\epsilon. \quad (1)$$

Nuisance parameter  $\epsilon$  takes into account systematic errors on effective area, etc.  $\sigma_\epsilon \sim 20\%$  for IceCube.

# Advanced IceCube Likelihood for Model Testing

Simplest way to do anything is to first make it a counting problem. . .

Compare observed number of events  $n$  and predicted number  $\theta$  for each model, taking into account error  $\sigma_\epsilon$  on acceptance:

$$\mathcal{L}_{\text{num}}(n|\theta_{\text{BG}} + \theta_{\text{sig}}) = \frac{1}{\sqrt{2\pi}\sigma_\epsilon} \int_0^\infty \frac{(\theta_{\text{BG}} + \epsilon\theta_{\text{sig}})^n e^{-(\theta_{\text{BG}} + \epsilon\theta_{\text{sig}})}}{n!} \frac{1}{\epsilon} \exp\left[-\frac{1}{2}\left(\frac{\ln \epsilon}{\sigma_\epsilon}\right)^2\right] d\epsilon. \quad (1)$$

**Then:** upgrade to full unbinned likelihood with number ( $\mathcal{L}_{\text{num}}$ ), spectral ( $\mathcal{L}_{\text{spec}}$ ) and angular ( $\mathcal{L}_{\text{ang}}$ ) bits:

$$\mathcal{L} = \mathcal{L}_{\text{num}}(n|\theta_{\text{signal}+\text{BG}}) \prod_{i=1}^n \mathcal{L}_{\text{spec},i} \mathcal{L}_{\text{ang},i} \quad (2)$$

All available in DarkSUSY v5.0.6 and later: [www.darksusy.org](http://www.darksusy.org)

# CMSSM model reconstruction with IceCube event data

Benchmark recovery with 22-string IceCube WIMP-search neutrino events + full likelihood:

**Mock signal:** 60 events,  $m_\chi = 500$  GeV, 100%  $\chi\chi \rightarrow W^+W^-$

(PS, Savage, Edsjö & The IceCube Collaboration, *JCAP*, 1207.0810)

# Example of Combined Direct + Indirect + LHC constraints

## Base Observables

## 2 Progress

- Gamma-rays
- Neutrinos
- CMB constraints

## 3 Future Challenges

- Respectable LHC likelihoods
- Statistical/numerical issues
- Parameter space  $\rightarrow$  Theory space

# Generalised DM CMB likelihood functions

Simple CMB likelihood function, for

- Any combination of annihilation or decay channels
- Any dark matter mass
- Any decay lifetime/annihilation cross-section

→ just requires interpolating one number in a table.

Cline & PS, *JCAP*, 1301.5908, using

- CMB energy deposition from
  - Slatyer (*PRD*, 1211.0283)
  - Finkbeiner et al (*PRD*, 1109.6322)
- PYTHIA annihilation/decay spectra from
  - Cirelli et al (PPPC4DMID; *JCAP*, 1012.4515)

# Generalised DM CMB likelihood functions

Simple CMB likelihood function, for

- Any combination of annihilation or decay channels
- Any dark matter mass
- Any decay lifetime/annihilation cross-section

→ just requires interpolating one number in a table.

$f_{\text{eff}}$  for annihilation:

$$\ln \mathcal{L}(\langle \sigma v \rangle | m_\chi, r_i) = -\frac{1}{2} f_{\text{eff}}^2(m_\chi, r_i) \lambda_1 c_1^2 \left( \frac{\langle \sigma v \rangle}{2 \times 10^{-27} \text{cm}^3 \text{s}^{-1}} \right)^2 \left( \frac{\text{GeV}}{m_\chi} \right)^2 \quad (3)$$

# Generalised DM CMB likelihood functions

Simple CMB likelihood function, for

- Any combination of annihilation or decay channels
- Any dark matter mass
- Any decay lifetime/annihilation cross-section

→ just requires interpolating one number in a table.

$f_{\text{eff}}$  for annihilation:

$$\ln \mathcal{L}(\langle \sigma v \rangle | m_\chi, r_i) = -\frac{1}{2} f_{\text{eff}}^2(m_\chi, r_i) \lambda_1 c_1^2 \left( \frac{\langle \sigma v \rangle}{2 \times 10^{-27} \text{cm}^3 \text{s}^{-1}} \right)^2 \left( \frac{\text{GeV}}{m_\chi} \right)^2 \quad (3)$$

$\eta$  for decay:

$$\ln \mathcal{L}(\tau | m_\chi, r_i) = -\frac{1}{2} \left( \frac{\delta\Omega}{\Omega_{\text{DM}}\tau} \right)^2 \eta^2(\tau, m_\chi, r_i) \quad (4)$$

## Generalised DM CMB likelihood functions

## Simple CMB likelihood function, for

- Any combination of annihilation or decay channels
- Any dark matter mass
- Any decay lifetime/annihilation cross-section

→ just requires interpolating one number in a table.

# The LHC likelihood monster

Time per point:

$\mathcal{O}(\text{minute})$  in **best** cases

# The LHC likelihood monster

Time per point:

$\mathcal{O}(\text{minute})$  in **best** cases

Time per point for global fits to converge:

$\mathcal{O}(\text{seconds})$  in **worst** cases

# The LHC likelihood monster

Time per point:

$\mathcal{O}(\text{minute})$  in **best** cases

Time per point for global fits to converge:

$\mathcal{O}(\text{seconds})$  in **worst** cases

Challenge:

About 2 orders of magnitude too slow to actually include LHC data in global fits properly

# Taming the LHC monster

## Zeroth Order Response:

“Stuff it, just use the published limits and ignore the dependence on other parameters”

# Taming the LHC monster

## Zeroth Order Response:

“Stuff it, just use the published limits and ignore the dependence on other parameters”

Obviously naughty – plotted limits assume CMSSM, and fix two of the parameters

- Don't really know dependence on other parameters
- Don't have a likelihood function, just a line
- Can't use this at all for non-CMSSM global fits – e.g. MSSM-25

SuperBayeS

# Taming the LHC monster

## First Order Response:

“Test if things depend on the other parameters (hope not),  
re-simulate published exclusion curve”

# Taming the LHC monster

## First Order Response:

“Test if things depend on the other parameters (hope not),  
re-simulate published exclusion curve”

Not that great, but OK in some cases

- At least have some sort of likelihood this time
- Still a bit screwed if things do depend a lot on other parameters, but
- allows (potentially shaky) extrapolation, also to non-CMSSM models

Fittino, Mastercode

# Taming the LHC monster

## Second Order Response:

“That’s ridiculous. I’ve never met a calculation I can’t speed up.  
There must be some way to have my cake and eat it too”

# Taming the LHC monster

## Second Order Response:

“That’s ridiculous. I’ve never met a calculation I can’t speed up.  
There must be some way to have my cake and eat it too”

Maybe – this is the challenge.

- Interpolated likelihoods (how to choose nodes?)
- Neural network functional approximation (how to train accurately?)
- Some sort of smart reduction based on event topology?
- Something else?

Balázs, Buckley, Farmer, White et al (1106.4613, 1205.1568)

# Outline

- 1 The Problem
- 2 Progress
  - Gamma-rays
  - Neutrinos
  - CMB constraints
- 3 **Future Challenges**
  - Respectable LHC likelihoods
  - **Statistical/numerical issues**
  - Parameter space  $\rightarrow$  Theory space

# Scanning algorithms

Convergence remains an issue, especially for profile likelihood  
Messy likelihood  $\Rightarrow$  best-fit point can be (and often is) easily missed  
(Akrami, PS et al *JHEP*, 0910.3950, Feroz et al *JHEP*, 1101.3296)

- frequentist CLs are off, as isolikelihood levels are chosen incorrectly
- can impact coverage (overcoverage, or masking of undercoverage due to non- $\chi^2$  TS distribution)
- need to use multiple priors and scanning algorithms (one optimised for profile likelihoods?)

# Coverage

[Statistical aside]

**Test statistic:** a measure on data used to construct statistical tests (e.g.  $\chi^2$ ,  $\ln\mathcal{L}$ , etc.)

**Coverage:** the percentage of the time that a supposed 'x%' confidence region actually contains the true value

- Distribution of the test statistic and design of the test it's used in determine coverage.
- $p$ -value calculation *requires* the test statistic distribution to be well known.

We don't *\*really\** know the distribution of our test statistic in BSM global fits, as it is too expensive to Monte Carlo

- coverage is rarely spot-on unless mapping from parameters to data-space is linear  
(Akrami, Savage, PS et al *JCAP*, 1011.4297, Bridges et al *JHEP*, 1011.4306, Streve et al *PRD*, 1201.3631)
- $p$ -value assessments of goodness of fit should be viewed with serious scepticism ( $\rightarrow$ MasterCode)

# Outline

  - Neutrinos
  - CMB constraints
- 3 Future Challenges
  - Respectable LHC likelihoods
  - Statistical/numerical issues
  - Parameter space  $\rightarrow$  Theory space

# CMSSM, SMS $\neq$ BSM

(SMS = Simplified Model Spectrum)

Want to do model comparison to actually work out which theory is right. . .

Challenge:

How do I easily adapt a global fit to different BSM theories?

# CMSSM, SMS $\neq$ BSM

(SMS = Simplified Model Spectrum)

Want to do model comparison to actually work out which theory is right. . .

## Challenge:

How do I easily adapt a global fit to different BSM theories?

Somehow, we must recast things quickly to a new theory

- data
- likelihood functions
- scanning code ‘housekeeping’
- even predictions

$\Rightarrow$  a new, very abstract global fitting framework

# Hitting the wall

Issues with current global fit codes:

- Strongly wedded to a few theories (e.g. constrained MSSM / mSUGRA)
- Strongly wedded to a few theory calculators
- All datasets and observables basically hardcoded
- Rough or non-existent treatment of most experiments (astroparticle + collider especially)
- Sub-optimal statistical methods / search algorithms
- $\implies$  *already hitting the wall on theories, data & computational methods*

# GAMBIT: a *second-generation* global fit code

GAMBIT: **G**lobal **A**nd **M**odular **B**SM **I**nference **T**ool

Overriding principles of GAMBIT: flexibility and modularity

- General enough to allow fast definition of new datasets and theoretical models
- Plug and play scanning, physics and likelihood packages
- Extensive model database – not just small modifications to constrained MSSM (NUHM, etc), and not just SUSY!
- Extensive observable/data libraries (likelihood modules)
- Many statistical options – Bayesian/frequentist, likelihood definitions, scanning algorithms
- A smart and *fast* LHC likelihood calculator
- Massively parallel
- Full open-source code release

# The GAMBIT Collaboration

<sup>†</sup>PI

# Closing remarks

- Robust analysis of dark matter and BSM physics requires multi-messenger global fits
- Lots of interesting astroparticle observables to include in global fits
- Quite a bit of technical (statistical/computational) detail to worry about
- GAMBIT is coming

# Outline

# Prospects for detection in the MSSM-25

## 86-string IceCube vs Gamma Rays

(Silverwood, PS, et al, JCAP, 1210.0844)
